

Android – Day 1 Project description

In this project, you build a single page Android app, *MovieSearch*, with the following functionality:

1. The user enters words in a title of a (some) movie(s).
2. The words are used as an http query into a movie database (web service), which returns a collection of movies that match the given query.
3. The app displays the first movie title found.

The UI should look (something like) this:

You should start off by using the skeleton Droid project, which is already a part of the solution you handed in at the end of last week. For communicating with the web service, you should be able to use your code from the PCL and/or a shared project.
